DISTANCE EDUCATION IN THE PERSPECTIVE OF
GLOBAL ISSUES AND CONCERNS

Jan Visser¹

International Development: The Broad Context

The history of international development is more than 50 years old. The origin of its pre-history may be located hundreds of years earlier, when the efforts of navigators and new conceptualizations by scientists started changing our idea of the world and of our place within it (e.g. Boorstin, 1985; Koestler, 1959). Those who had the economic power and who therefore had access to the technology of the day, discovered that they were not alone in the world and that other peoples – for a long time seen as essentially different and invariably inferior – co-inhabited the planet. Different forms of cohabitation, often of an exploitative nature, emerged in the process of colonization that followed. That period came to an end during the third quarter of the last century. The movement towards emancipation and decolonization, largely driven by the formerly oppressed, led to the recognition among those who eventually relinquished power that not everything in the world was right. In fact, it brought to the forefront that there were great inequalities that conflicted with long held moral convictions – convictions that had, until then, been solely applied (and even then only partially) to the societies to which those who held the

¹ The author is founder and president of the Learning Development Institute (LDI). He is also the former director for Learning Without Frontiers (LWF) at UNESCO (United Nations Educational, Scientific and Cultural Organization). Information about LDI and LWF is available online at http://www.learndev.org and http://www.unesco.org/education/lwf/, respectively. This chapter is written against the backdrop of the author’s involvement in the development of distance education in Africa and elsewhere since the early nineteen-seventies as well as his later involvement in broadening the scope of such pursuits in the context of LWF and LDI. Any opinions expressed in this chapter are entirely those of the author and do not necessarily reflect official policy of UNESCO or the Learning Development Institute.
convictions pertained. Such inequalities, it was realized, were immoral and they threatened stability. A new world order was called for.

Initial ideas about development focused on technology transfer. The world was seen as polarized between developed and underdeveloped nations (terms that were later replaced by industrialized and developing nations). The rationale underlying the development philosophy was a simple one: Those parts of the world that saw themselves as developed had little to learn from those that were in need of development; contrariwise, the developed nations felt the obligation to share their knowledge and skills with those whose different state of development was assumed to have been the consequence of the lack of such knowledge and skills. In other words, there was a formidable urge on the part of some to teach and an assumed great need on the part of hundreds of millions of others to learn. While the development discourse reflecting this philosophy has become more nuanced over the decades, much of its basic assumptions are still very much alive.

The above general context is provided as a backdrop for the discussion in this chapter of the development of distance education as a contributing factor to building a better world. Within that perspective, the following four statements are offered as an advance organizer for thinking the issue through:

1) The development effort undertaken over the past half century has, to a considerable extent, focused on creating and improving education systems, modeled after the education systems of the industrialized West.

2) The extent of the educational needs (defined as implied by the previous statement) in developing nations has been so enormous – compared to the available resources – that
traditional modalities to meet those needs could not be but insufficient. The search for alternatives, including distance education, was a natural consequence of this recognition.

3) The visions underlying the concepts of development and education have a tendency towards explaining the world, its history, and the possibilities to shape its future, in linear terms. They are also based on the assumed superiority of the knowledge systems of the so-called developed world over so-called local or indigenous knowledge systems. The short history of international development of the past half century justifies questioning the validity of those visions.

4) The global issues and concerns prevailing at the time when the international development effort took off were still limited in scope and biased towards the problems that had thrown the world into turmoil during the late nineteen-thirties and early nineteen-forties. It took another half century to discover that the world was infinitely more complex than we had ever thought. A more comprehensive picture of global issues and concerns has started to emerge during the last decade of the twentieth century, but we are far from having a handle on how to deal with the implications of those issues from a learning point of view.

Scope of This Chapter

This chapter looks at the role of distance education in the perspective of global issues and concerns. This topic normally receives little – if any – attention in the literature of the field. Yet, as I shall argue, it is closely linked to the very reasons why distance education became an important dimension of the international development agenda. I shall particularly focus on the discrepancy between the established practice of distance education and the overriding purposes
for educational development. This will then lead to a critique of the field as it currently stands. It should be noted, though, that such a critique is equally valid for most other aspects of educational development.

The critique of distance education in the above respect is linked to the larger question of the meaning of learning. After an analysis of the development of distance education in the next two sections, I shall therefore elaborate on the need to revisit the meaning of learning as it relates to the demands of our time. Having done so will allow holding current perceptions of distance education against the light of an enhanced vision of learning. This, in turn, will lead to recommendations about what to emphasize and what to de-emphasize in developing the field further.

**Taking a Closer Look at the Problem**

The development of distance education globally, and particularly in the developing world, has largely been driven by the desire to overcome the shortcomings of established systems of schooling. The literature of the period when distance education started to position itself as a serious alternative to or complement of school-based offerings, would often do so by contrasting distance education – or, as it used to be called, correspondence education and, in some other cases, radio or TV education – with what was seen as traditional or conventional education (e.g. Edström, Erdos & Prosser, Eds., 1970; Erdos, R. F., 1967; Faure *et al.*, 1972; Perraton, Ed., 1976; Young, Perraton, Jenkins & Dodds, 1980).

Different considerations motivated the emergence of distance education as a significant alternative. There was in the first place the growing awareness of the injustice inherent in the fact
that a large proportion of the world’s population was deprived of the opportunities to learn, as
offered by schools, that were commonly available to everyone in other parts of the world.

At the same time there was the expectation that “new media” would usher in an era of
until then unimagined possibilities to overcome the barriers of the past. In an address to the State
Department on 20 August 1971, Arthur C. Clarke expressed it this way: “The emerging countries
of what is called the Third World may need rockets and satellites much more desperately than
the advanced nations which built them. Swords into ploughshares is an obsolete metaphor; we
can now turn missiles into blackboards” (Clarke, 1992, p.208).

Hope and vision were accompanied by the desire to gather evidence in support of the
claims that media, and the instructional design principles underlying their use, could indeed help
to overcome the formidable obstacles faced by educational leaders and planners in developing
countries. Most notable perhaps in that context was a worldwide research project undertaken by
UNESCO’s International Institute for Educational Planning in 1965 and 1966 under the
leadership of Wilbur Schramm, resulting in the landmark publication of three volumes on “New
media in action: Case studies for planners” and a companion volume on “The new media: Memo
to educational planners” (UNESCO: International Institute for Educational Planning, 1967a &
1967b). Other prominent sources that reflect the thinking of that time regarding the use of media
for educational purposes are Schramm’s (1977) “Big media, little media,” Jamison &
McAnany’s (1978) “Radio for education and development,” and Jamison, Klees & Wells’s

At the same time that the media started to position themselves as a challenging
opportunity to solve the educational problems of the developing nations, the instructional design
field was coming of age with such classics as Gagné’s “The conditions of learning” (first
published in 1965) and Gagné and Briggs’s “Principles of instructional design” (first published in 1974), giving confidence that the process of making people learn and ensuring that their learning achievements would match their originally identified learning needs was one that could be controlled in the first place as well as managed within a considerably wider range of parameters than those traditionally considered. Particularly, it was found that that process was not necessarily or exclusively dependent on a human facilitator.

All the above factors taken together provided a powerful reason to search for the solution of the world’s educational problems in settings beyond those of the conventional schooling practice. Naturally, it also raised questions as to whether any of the contemplated alternatives to traditional schooling would be better, or worse, or at least equally good as what they were supposed to replace or complement.

The inadequacy of the traditional education provision is usually referred to in sources such as those mentioned earlier on, in two respects. The most obvious shortcoming, then as well as now, is that traditional schooling systems cater for only a limited part of the audience they are supposed to serve, resulting in great inequity among the inhabitants of our planet in how they are allowed to see themselves and act as participants in a world that is larger than their immediate environment. It led Julian Huxley, Executive Secretary of the Preparatory Commission for UNESCO in 1946, later UNESCO’s first Director-General, to consider that “Where half the people of the world are denied the elementary freedom which consists in the ability to read and write, there lacks something of the basic unity and basic justice which the United Nations are pledged together to further” (cited in UNESCO, 2000, p. 27). While Huxley recognized that various factors are responsible for such inequity, he saw what was then called ‘Fundamental Education” (p. 27) as an essential contributing factor to “the wider and fuller human
understanding to which UNESCO is dedicated” (p. 27). The problem referred to by Huxley is far from over. According to figures in the latest issue of the World Education Report (UNESCO, 2000) the world total of illiterates still stands at 875 million, i.e. a very significant proportion of the six billion inhabitants of our planet, and the number of children in the primary-school-age who do not go to school continues to be of the order of magnitude of one hundred million.

However, access to learning opportunities was not the only problem. The other major shortcoming of the schooling system, recognized in at least part of the literature referred to earlier (e.g. Faure et al., 1972; Young, Perraton, Jenkins & Dodds, 1980), had and has to do with the schooling tradition itself, particularly as regards the kind of learning it instills in students, the social consequences of expectations generated by the school, and the often poor relevance of what is being learnt for those who learn as well as for the development context they are part of.

The former of the two deficits is of great concern to humanity in the context of the fundamental human right to education. That right is specified in Article 26 of the Universal Declaration of Human Rights. The World Education Report 2000 (UNESCO, 2000) gives ample coverage of how that right and its implications have been perceived and discussed since the Declaration was adopted and proclaimed by the General Assembly of the United Nations on December 10, 1948.

It is important in the context of this chapter that the Declaration clearly links education to the overriding purpose that it should lead to “the full development of the human personality and to the strengthening of respect for human rights and fundamental freedoms” (cited in UNESCO, 2000, p. 16).

**Article 26**

1) Everyone has a right to education. Education shall be free, at least in the elementary and fundamental stages. Elementary education shall be compulsory. Technical and professional education shall be made generally available and higher education shall be equally accessible to all on the basis of merit.  
2) Education shall be directed to the full development of the human personality and to the strengthening of respect for human rights and fundamental freedoms. It shall promote understanding, tolerance and friendship among all nations, racial or religious groups, and shall further the activities of the United Nations for the maintenance of peace.  
3) Parents have a prior right to choose the kind of education that shall be given to their children.

Education, in the view of the Declaration, particularly its second paragraph, therefore transcends the mere concern with the acquisition of particular skills and pieces of knowledge, relating it to the human ability to live in harmony with oneself, one’s environment and one’s fellow human beings. Consequently, the deficit of the school system should not be interpreted solely in terms of the lack of opportunity to acquire such competencies as the ability to read and write, but rather in terms of how such, and other, abilities “promote understanding, tolerance and friendship among all nations, racial and religious groups,...and the maintenance of peace” (p. 16).

In so far as distance education is seen as a way of overcoming the shortcomings of the school systems, it should, at least in the context of a discussion of the human right to education, be judged by these same standards. In other words, the primary question to be asked is not how the development of distance education has contributed to improved access to and participation in education, and at what cost this was achieved. Rather, the question should be: Does distance education contribute to a better world? Put this way, the question also includes concerns that pertain to the second major area identified above, the one that motivated the distance education field to see itself as an opportunity, not only to open up possibilities for learning to the as yet unreached, but equally to do so in ways that would be responsive to questions about the purposes of education and the meaning of learning, as well as, in that context, the critique of the existing schooling tradition.

**Means or End?**

Article 26 of the Universal Declaration of Human Rights represents a rare instance in the development of international discourse in the area of educational policy where an unequivocal reference is made to the purposes of education beyond the scope of particular content concerns.
It clearly advances the perspective that education is not an end in itself but rather a means towards how we, as humans, collectively shape the ways in which we socially organize ourselves, live together, and share the resources of our planet. The terms in which that perspective is formulated reflect the concerns of the post-World War II era, when the Declaration was drafted. The ensuing debate and subsequent international frameworks developed over the past half century have both consolidated, strengthened and expanded the original vision of Article 26, allowing it to evolve and become responsive to global concerns, in addition to the original ones, that are now felt to be essential for a stable and harmonious world order. Sustainable development and the eradication of poverty are but two of the global concerns that were not originally expressed in an explicit way in Article 26 but that have since become recognized as key issues.

Particularly the last decade of the past century has seen a renewed interest in and discussion of the purposes of education in the context of global issues and concerns. Those issues and concerns have to do with such matters as our fragile environment; the growth of the world population; our ability to interfere technologically and scientifically with who we are; the depletion of the world’s resources; the advancement of peace, not as the mere absence of war, but as a culture, a set of values, attitudes, traditions, modes of behavior and ways of life (United Nations, 1999); as well as the impact of pandemic diseases. An impressive range of world conferences – the World Education Report 2000 (UNESCO, 2000) mentions 15 of them, starting with the World Conference on Education for All in Jomtien, Thailand in 1990 and ending with the World Science Conference in Budapest, Hungary in 1999 – has helped to put the crucial issues of our time on the agenda of the international community, while seeking to understand how education can contribute to addressing them. Two major UNESCO reports produced during
the nineteen-nineties – “Education, The treasure within” (Delors et al., 1996) and “Our creative diversity” (Pérez de Cuéllar et al., 1996) – should be seen in the same light.

The recent renewed attention to the overriding purposes of education should come as no surprise. For the first time in several million years of hominid development, the human species faces challenges of an order of magnitude it has never had to deal with before. I have argued elsewhere (J. Visser, 2001), drawing also on the views of authors such as Koestler (1989/1967), Pais (1997) and Sakaiya (1991), how these challenges are part of a context of change patterns that are unique for our times and markedly different from those that characterized the human condition a mere couple of decades ago. They require human beings to be able to function in entirely unpredictable situations. Lederman (1999, April) thus calls for schools to

    look across all disciplines, across the knowledge base of the sciences, across the wisdom of the humanities, the verities and explorations of the arts, for the ingredients that will enable our students to continually interact with a world in change, with the imminence of changes bringing essentially unforeseeable consequences.

It needs no arguing that, by extension, the same rationale should apply to any alternative to the school, such as distance education systems that are being put into place to overcome the shortcomings of the school. However, it would be a mistake to look at the school and its alternatives, as a panacea for the complex set of problems referred to above or to look at it in isolation. Schooling is not the same as learning. Schooling plays a role, and it can play a much more useful and effective role if it were profoundly reconceptualized, but that role is limited and relative to the role played by other factors that condition the learning environment at large. To appreciate the relative importance of the schooling tradition – including how that tradition is reflected in the practice of distance education – as well as to critically do away with those
elements of the tradition that violate the attainment of agreed purposes, we must first develop a more comprehensive picture of what learning is.

**Learning: The Comprehensive Picture**

One of the greatest impediments to the development of a learning society is the difficulty we all have to liberate ourselves from the preconceptions about learning with which we grew up. This point was brought home in a series of transdisciplinary debates, promoted and conducted under the auspices of UNESCO and the Learning Development Institute. The first of these debates took place under the title “Overcoming the Underdevelopment of Learning” at the Annual Meeting of the American Educational Research Association (AERA) in Montreal, Canada in 1999 (J. Visser et al., 1999). It was followed by a workshop with diverse inputs at the National Convention of the Association for Educational Communications and Technology (AECT) in Long Beach, CA, in February 2000, and a Presidential Session on “In Search of the Meaning of Learning” at the subsequent International Conference of the AECT in Denver, CO, in October 2000. The latter debate, as reflected in the papers and statements that were generated through it, is available on the World Wide Web site of the Learning Development Institute (Meaning of Learning [MOL] project, n.d.).

Further insight can be derived through disciplined inquiry into learning as perceived by those who learn. Such inquiry typically focuses on the entire human being or on the activity of an entire collaborative entity in a cultural-historical perspective. It thus involves units of analysis whose order of magnitude by far transcends the habitual research perspective, which tends to focus on learning tasks that are narrowly defined in scope and time and that may involve only very specific learning behaviors assumed to be undertaken by isolated individuals. (A similar
point is made by Cole, 1991, regarding the need to redefine the unit of analysis in the study of socially shared cognitions). Research such as referred to above, was recently reported by Y. L. Visser and J. Visser (2000) in their analysis of so-called learning stories. That research focused on the perceptions about learning from the perspective of individuals. John-Steiner (2000) went beyond the individual level, making the collaborative team or partnership the unit of analysis, in her study of creative collaboration.

The preliminary results reported by Y. L. Visser and J. Visser (2000) indicate that the advance towards meaningful learning should focus on:

- The development of felt ownership of knowledge.
- The emotional integration of any particular learning experience in an individual’s perceived lifespan development.
- The generative nature of learning.
- The real-life context as the natural habitat for learning.
- The interaction with the learning of others as a basis for one’s own learning.
- The power of learning to turn negative self-perceptions into positive ones.
- The discovery of persistence as a strategy to manage life’s challenges.

Such learning was found to be particularly facilitated when initially negative conditions could be transformed into positive challenges; when role models were present or emotionally significant support was available in the environment of the learner; or when there were opportunities for independent exploration of one’s learning and metacognition.

Much in the analysis of the above-referred individual learning stories points towards the importance of context, particularly the social, cultural and historical integration of the learning individual. John-Steiner’s (2000) analysis of cases of creative collaboration reinforces, makes
more explicit, and enhances that notion. In analyzing her cases, she builds a strong argument against the prevalent cultural model of the solitary creative mind and stresses the principle that “humans come into being and mature in relation to others” (p. 187). Interdependence, or social connectedness, is thus a crucial dimension of any learning context, a dimension that needs to be balanced against that of the learner’s individuality.

Feldman (2000), shedding foresight on the importance of John-Steiner’s work, refers to the search for “balance between individuality and social connectedness” (p. xii) as the central theme of the current century, contrasting it with the past century’s focus on “intellectual development that placed the lone seeker of knowledge…at the center of the developmental process” (p. ix). Such a shift of focus comes at a good time. The global issues and concerns considered in this chapter are too involved and too complex to be addressed by solo efforts. They call for visions of learning that are built around notions of sustained collaboration and dynamically evolving dialectic relationships between individuals and communities. Such visions have only marginally to do with the content of learning. Rather, they impact on how people learn and therefore on how the learning landscape should be restructured. They are an equally powerful motivation to start thinking differently about learning, “undefining” the concept, as I have proposed elsewhere (J. Visser, 2001), and recasting it as a disposition to dialogue – expressed at different levels of complex organization— for constructive interaction with change.

A final important contribution to creating comprehensive visions of learning can be found in the efforts to review significant research findings of the past and present, emanating from different disciplines, with a view to summarizing them in the framework of transdisciplinary major themes. An excellent example of such an effort is the work undertaken by the Committee on Developments in the Science of Learning of the National Research Council (Bransford,
Brown & Cocking, Eds.,1999). The Committee identifies five major themes that are important in changing our conceptions of learning. They have to do with: (1) how we develop coherent and accessible structures of information; (2) the ways in which we develop expertise and acquire the capability to solve problems we have never dealt with before; (3) new insights in learning and mental development at the initial stages of the human lifespan; (4) the role played by metacognitive and self-regulatory processes; and (5) the relation between learning and the cultural and community context in which symbolic thinking emerges.

Achievements To Date

Earlier in this chapter I have referred to Article 26 of the Universal Declaration of Human Rights as a case in point where there has been broad consensus within the international community about the crucial importance of a global concern and the potential role of education – and thus also distance education – in addressing it. Considering that many more such global concerns have lately been added to the shared conscience of humanity, it is of interest to look back and ask ourselves what has been done. What we see is not encouraging.

There is no doubt that considerable achievements in implementing Article 26 mark the more than five decades since the proclamation of the Universal Declaration of Human Rights. The field of distance education can claim credit for at least part of those achievements. However, as the World Education Report 2000 (UNESCO, 2000) points out, surprisingly little of what was achieved reflects a concern with more than increasing the numbers of those who benefit from structured learning opportunities. Or, in the words of the report:

While . . . there has been a great deal of progress worldwide over the past half century towards implementation of the right to education in terms of access to education, it
nevertheless remains that the vision that came to be embodied in Article 26 of the Universal Declaration of Human Rights was not just a quantitative one. It was also a qualitative one concerning the purposes and hence contents of education (p. 74).

Unfortunately, the language of the above quote is confusing as it equates “purpose” and “content.” For the discussion in this chapter it is important to make a clear distinction between those two concepts. The concept “content” connotes subject matter knowledge, which may easily be interpreted as a commodity traded between those who possess it, the teachers, and those who wish to acquire it, the students. Within the context of the purposes of education, content is only one element that may or may not contribute to attaining a particular purpose. The following example may elucidate this.

It is commonly thought that the teaching of subjects such as history and geography can have a potentially important impact on how students will think about and treat their fellow human beings pertaining to other cultures or whose existence is marked by different histories. Such a thought may indeed have motivated the 1949 International Conference on Public Education, which, apparently still mindful of the words of the Universal Declaration, recommended “the teaching of geography as a means of developing international understanding” (cited in UNESCO, 2000, p. 77). While I shall be critical, in what follows, of the rather naïve assumptions inherent in this recommendation, it should also be noted that this was one of only two such International Conferences, held during the twenty years following the adoption of the Universal Declaration of Human Rights, that produced anything reminiscent of the global issues raised in the Declaration.

It is unlikely, though, that the simple introduction of a piece of curriculum, or the restructuring of existing curriculum, in accordance with the above idea will more than marginally
contribute to the earlier-mentioned larger goal of international understanding as long as “teaching” means no more than “transmission of pieces of knowledge.” Much more is needed in changing attitudes. Both Bandura (1969) and Gagné (1985) argue that human modeling and practicing of the model are essential. In the case of our example, the content of disciplines like Geography and History may be about as relevant to being exposed to models of human behavior, and being encouraged to practice them, as is the content of disciplines such as Physics, Chemistry, Biology or Mathematics.

In fact, as a segment of the traditional school curriculum, the latter set of disciplines may be more adequate, if purposefully taught, in a strategy to attain a broad goal like international understanding. First of all, practitioners of the natural sciences and mathematics are known for their disregard of any conventions that would limit them in their pursuit of the advancement of knowledge in their field. This is exemplified by how, during the coldest periods of the cold war, there has always been scientific exchange across the so-called “iron curtain.” Moreover, even as the Nazis rose to power in Europe, and the Second World War ravaged the continent and its scientific community, interests within the latter ensured that after the end of the war, wounds could quickly be healed. Numerous accounts of the lives of scientists and the development of science in the twentieth century (see, for instance, Pais, 1991, and Perutz, 1998) describe in detail, and with great attention to the human qualities involved, what was at stake.

What the above argument comes down to is that appropriate procedures, involving apparently unrelated content, can very well serve the purpose of addressing global issues, such as the development of tolerance and international understanding. The proper teaching of science could bring to life the human models that Gagné (1985) and Bandura (1969) call for. Practicing those models can well be undertaken in the context of collaborative projects across geopolitical
and other boundaries among students (sometimes also involving practicing professional scientists) in areas like environmental science. Current technologies facilitate the building of such learning communities.

**Challenges Ahead**

The prevailing focus in the rhetoric of distance education has for a long time been on such issues as cost-effectiveness, economies of scale, and parity of esteem, all of them defined with reference to the traditional school context. This has profoundly left the thinking about distance education in the fold of the classroom model as the dominant pattern. Despite the advent of powerful new technologies and the increasing realization that the problems of today are fundamentally different in nature from yesterday’s problems, there is a disturbing lack of imagination in how discourse and practice remain locked up in the conceptions of the past. The abundant use of such terms as “online classroom” and “virtual school” is but one expression of how powerful a place the ideas of school and classroom continue to occupy in our language, and thus our thought processes. But even when new terms are introduced, such as e-learning, the reality behind them is often as sadly representative of the unaltered past – cast for the occasion in new molds – as the choice of the term itself is testimony to the absence of creative thinking.

Simonson (1999) calls for strategies that provide “different but equivalent learning experiences” (p. 29) to learners in face-to-face classes and in online classrooms. However, this so-called equivalence theory, while recognizing the differences in instructional contexts between the two modalities concerned, does little to promote a fundamental rethinking of what goes on inside the learning space, whether virtual or real.
Contrasting with the above is the sense of critical appreciation of the state of distance education in the world, which recently emanated from a group of 23 experts from around the globe, convened by UNESCO, at a meeting in Karlsruhe, Germany. One of the recommendations made by that group states:

Now that distance education has reached its desired level of recognition and esteem vis-à-vis traditional educational alternatives, time has come for it to take a critical look at itself, asking questions about how existing experience fits in with the requirements of and opportunities inherent in present day society and how it reflects the current state of knowledge about how people learn. It is recommended that such a critical attitude drive any future development in the field of distance education in UNESCO and its Member States (UNESCO, 2001, February, p. 4).

The group framed its recommendation with particular reference to “the evolving notions of a learning society and of lifespan human development” (p. 4). It furthermore recommended that distance education be seen as “just one modality – or set of modalities – among many others that together shape the learning environment, which is multi-modal and aware of multiple dimensions of human intelligence, at the cognitive, meta-cognitive and affective level” (p. 4).

In connection with the above recommendation, the group of international experts convened by UNESCO devoted particular attention to the opportunities inherent in the currently available technologies. Market forces, rather than considerations about how and why people learn, determine that such technologies will be used. In the absence of clear thinking, their use will likely result in the replication of past practices by new means. At best this means that nothing changes; at worst it means that with accelerated speed, and more forcefully than ever,
bad practices will be consolidated and reinforced. Or, in the words of the report (UNESCO, 2001, February):

The advent of the Internet and the invention of the World Wide Web have, supplemented by a wide and growing range of multimedia technologies, particularly during the past decade, fundamentally changed the equation of what is and what is not possible. It has particularly created opportunities for the rediscovery of learning as a dialogic and social process through which diverse people join in the creation of dynamic learning communities, collaborating with each other while using their full human potential to continually develop their capacity to stand prepared for an ever-changing world. Such a process is one of shared construction, which, while it may contain linear elements, is greatly enhanced if the learning environment allows building blocks – of different granularity – to be brought in flexibly, as they are needed. The possibility to create, store and subsequently retrieve for use or further processing such building blocks in digital format is an important asset of today’s technology. It awaits further exploration, particularly in the context of the [earlier referred] much needed reconceptualization of learning. In this process, the traditional roles of those who learn and those who facilitate other people’s learning are bound to change so fundamentally that terms like “student” and “teacher” become less appropriate to designate the actors in the learning environment. The human and social processes that can be created, while using these new technologies to attend in massive ways to the innate human need to learn, can and must take full account of research findings that have redefined learning as a process of participatory construction rather than as individual acquisition (pp. 5-6).
The group thus recommended the inclusion of experts in communication and information technology in collaborative multidisciplinary partnerships involved in the reconceptualization of learning. Without doing so, it argued,

there is the great risk that the use of improved technology will only reinforce and consolidate practices that, though unfortunately often part and parcel of established educational practice, have long been recognized to be counter to the development of humanity’s critical and creative capacity and of the human ability to confront the complex problems of today’s world (p. 6).

The latter observation resonates with Salomon’s (2000, June) criticism of “technocentrism,” which “totally ignores some crucial social and human factors” (p. 4). It leads him to observe that without taking these factors into account, “virtual distance learning . . . is in danger of yielding virtual results” (p. 4). To avoid this from happening, Salomon urges an emphasis on two things: tutelage and community of learners. The former aspect has received attention in L. Visser’s (1998) work on affective communication and in Gunawardena’s (1995) work on social presence. The latter aspect has been emphasized by the group of people who gathered initially around the ideas promoted by UNESCO’s Learning Without Frontiers (2000) program and who later converged around the vision of the Learning Development Institute (2001).

Complex Cognition for a Complex World

Gell-Mann (1994) refers to learning as a process in which complex adaptive systems, such as human beings, interact with other complex adaptive systems, making sense of regularities among randomness and allowing them to mutually adapt. In a similar vein, the report
of the Committee on Developments in the Science of Learning (Bransford, Brown and Cocking, Eds., 1999) affirms that “learning is a basic, adaptive function of humans” (p. xi). To understand that function, and thus the practice of its facilitation, account must be taken of the entire developing transdisciplinary knowledge base that has its roots in such widely diverse disciplines as “cognitive development, cognitive science, developmental psychology, neuroscience, anthropology, social psychology, sociology, cross-cultural research, research on learning in subject areas such as science, mathematics, history, and research on effective teaching, pedagogy, and the design of learning environments” (p. xxi). Broadening our conception of learning is an essential prerequisite if learning is to have relevant meanings in the context of adaptive human behavior regarding the global issues discussed in this chapter.

Learning, then, should be understood to mean more than what is implied by its regular reference to particular desired changes in human performance capability. In a broader sense, which includes the more specific meaning just mentioned, learning can be seen in relation to the unending dialogue of human beings with themselves, with their fellow human beings, and with their environment at large, allowing them to participate constructively in processes of ongoing change. In other words, learning must be “undefined.” A possible redefinition thus calls for human learning to be seen as “the disposition of human beings, and of the social entities to which they pertain, to engage in continuous dialogue with the human, social, biological and physical environment, so as to generate intelligent behavior to interact constructively with change” (J. Visser, 2001).

Few people would doubt that learning impacts on the human brain. However, that recognition should not be taken to mean that the individual human mind in isolation should be the prime focus of attention for educators, whether at a distance or in the face-to-face mode.
Quite to the contrary, it is increasingly recognized, e.g. by the collective of researchers that contributed to Salomon’s (Ed., 1993) explorations into the distributed nature of cognitions, that knowledge is socially constructed as a result of purposeful interaction among individuals in the pursuit of shared objectives that are situated in socio-cultural and historical contexts. Views such as those referred to above should perhaps not be seen as new or surprising, as Nickerson (1993) points out. Rather, they are a consequence of the ways in which, for a very long time, formal instructional practice has kept its eye trained on the individual. So strongly has that been the case that the reality of the communities to which those same individuals belong could no longer be seen. What used to be obvious thus became forgotten and now stands to be brought to the forefront again. Nickerson refers in this connection to Ulam (1991), who says: “Sometimes obvious things have to be repeated over and over before they are realized” (p.303). In this particular case, however, more is necessary than the frequent repetition of the obvious; the obvious must first be resuscitated.

To do so we must develop a vision of learning that is ubiquitous; unrelated to conditions such as age, time, space and circumstance of learning individuals; manifests itself not only in the behavior of individuals but at diverse levels of complex organization; and that, in whatever context it takes place, does so as part of a pattern of interrelated learning events occurring in what can best be called a “learning landscape.” Cognition is, and has always been, an ecological phenomenon. Being an ecological phenomenon, it is also evolutionary. The two notions are interrelated, as Levin (1999) points out. “Ecological interactions take place within an evolutionary context and in turn shape the ongoing evolutionary process” (p. 46).

Invoking terms such as “ecology” and “evolution” is not an exercise at inventing sophisticated metaphors. Webster’s Third New International Dictionary (Gove, 1993) defines
ecology as a “branch of science concerned with the interrelationship of organisms and their environments, esp. as manifested by natural cycles and rhythms, community development and structure, interaction between different kinds of organisms, geographic distribution and population alterations” (my emphasis). The origin of the word is, according to the Encyclopaedia Britannica (1999), the Greek “oikos,” which means “household, home, or place to live.” These descriptions apply as much to the world of learning entities as they apply to the world of living organisms. This should come as no surprise. The capability to make sense of regularity among randomness, which, according to Gell-Mann (1994), is the essence of learning, is also key to any life form’s chances of survival in an environment populated with other forms of life.

My use of the term “learning landscape” may be taken to be metaphorical. Like the real landscape, the learning landscape is the result of, on the one hand, the natural – that is ecological – interplay of different learning entities seeking to establish themselves in the midst of others and, on the other, of the consciously planned action on the part of some actors to reshape and adjust what nature tends to produce. I use the term “landscape” deliberately because of its connotations, some of which are more poetic than operational. This, then, brings into play, in addition to the usual parameters of effectiveness and efficiency of the learning environment, also its aesthetic and ethical qualities. The planners and leaders whose actions impact on the learning landscape may well want to consider this extended meaning of the metaphor and look for beauty and harmony in the learning landscape as a major indicator for the quality of the ecology of cognition. It is probably no exaggeration to say that, so far, the work of governmental educational planning agencies, as well as of related entrepreneurial and institutional efforts, to create the infrastructural conditions for the facilitation of learning, leaves considerable room for improvement in terms of the need to be environmentally aware of what else happens in the
The term ‘learning landscape’ reflects well the idea of ‘complex cognition,’ a concept recently proposed by the author at a Santa Fe Institute seminar (J. Visser, 2000, November). Cognition is a complex phenomenon in the sense that it evolves according to the laws that govern the behavior of complex adaptive systems. The conditions that underlie such behavior are well known (see e.g. Gell-Mann, 1995; Holland, 1995) and the behavior itself can be seen to be present in such widely diverse systems as the stock market, the weather, or biological systems.

The notion that cognitions are distributed comes close to the idea of “complex cognition.” However, as Salomon (1993) points out in his editor’s introduction to the overview of thinking in this field presented in ‘Distributed cognitions: Psychological and educational considerations,’” the meaning attributed to the term ‘distributed cognitions’ differs considerably, depending on the theoretical perspective adopted by different researchers. On one end of the spectrum there is the view that “cognition in general should be...conceived as principally distributed,” the “proper unit of psychological analysis...[being] the joint...socially mediated action in a cultural context” (p. xv). This view deviates clearly from the common view that cognitions reside inside individuals’ heads. On the other end of the spectrum there is the conception that ‘‘solo’ and distributed cognitions are still distinguished from each other and are taken to be in an interdependent dynamic interaction” (p. xvi). This juxtaposition of views is resolved in the concept of complex cognition, which makes the distinction irrelevant, integrating the diverse points of view in a single notion. Cognition is individually owned and socially shared at the same time.
Distance Education in the Perspective of Global Issues and Concerns

Much of my argument in this chapter has refrained from focusing on distance education per se. I have done so deliberately. The problem area chosen as a guiding framework for the intellectual pursuits I made reference to, that of the interaction between humanity’s capability to deal with global concerns and the development of its capacity to learn, calls for a comprehensive approach that must not be restricted to the field of distance education alone. On the other hand, the question whether distance education may play a crucial role within such a comprehensive approach, is a relevant one. I shall explore that question in this final section. While trying to address it, I shall be particularly interested in looking at what kind of questions need to be asked and what different orientations need to be developed if distance education is to play such a role.

One of the overall conclusions of this chapter is that the phenomenon of learning is infinitely more involved and complex than assumed in most of our actions aimed at creating the conditions to promote and facilitate it. As our learning stories research suggests (Y. L. Visser & J. Visser, 2000), if significant learning does take place, it often does so rather despite than because of the conditions we created for it. I contend that this doesn’t have to be that way; that, in fact, we can be cleverer than we seem to be. To show such enhanced intelligence, our approaches must become bolder and our views must become more comprehensive.

The global issues and concerns referred to in this chapter – the profound questions about how we live together on our tiny planet and share its resources, sustaining life as we came to know it and became conscious of our place in it, playing our role in, how in time, perhaps, a next phase in its evolution may emerge – find no response in our designed learning systems. Yet, most people share these concerns and feel they can no longer be dismissed or simply be seen as an afterthought of our more specific attempts at developing human capacity. The history of how
the educational establishment, including the distance education variety of it, has failed to address such most crucial challenges as the ones inherent in Article 26 of the Universal Declaration of Human Rights is proof of the fruitlessness of attempts to use our traditional learning systems in an isolated fashion while dealing with global issues and concerns. Such attempts must be undertaken, as urged in the earlier quoted UNESCO report, in a wider framework, namely that of the learning society and of lifespan human development, taking full account of the convoluted ways in which humans learn (UNESCO, 2001, February).

The important question then is: How can distance education contribute to improving the ecological coherence of the learning environment so that it will allow meaningful learning to evolve in response to the crucial global issues and concerns that mark the beginning of the third millennium? The question branches off in a variety of directions, some of which will be highlighted below. To bring some order in the observations and conclusions that follow, I shall deal with them, respectively, at the levels of society at large; collaboration among institutions and organizations within society; the organization of specific institutions; and the learning process.

**Implications at the societal level**

At the level of society at large, the responsibility for the creation of the conditions of learning is a distributed one. This view contrasts with the common idea that such a responsibility resides solely or mostly with ministries or departments of education. Obviously, the latter idea comes from the misconception that education and learning are one and the same thing. It is important to make a distinction between the two and to look at the instructional landscape as a sub-landscape of the learning landscape.
Instruction is – or should be – a designed way to facilitate learning for specifically defined purposes. The preoccupation with instruction results in a wide variety of instructional opportunities. Within the conception, advocated in this chapter, that society at large is responsible for the totality of learning that goes on within it, the various instructional opportunities should be aware of each other and interconnect with each other. They form, as an organically interlinked whole of designed opportunities to learn, the instructional landscape.

The instructional landscape does not stand on its own. Many other sub-landscapes together make up the learning landscape, in a way similar to how Appundarai (1990) describes the dynamics of global diversity in terms of different “scapes.” Other sub-landscapes included in the learning landscape are, for instance, the media landscape (see Allen & Otto, 1996) and the socio-cultural organization landscape, of which the family is part. A truly ecologically functioning learning landscape will be characterized by the smooth integration among all the various sub-landscapes – together with their subordinated sub-landscapes – that compose the learning landscape.

Because of its potential flexibility and openness, distance education, as a modality, can play a very important role in bringing about ecological integration within the learning landscape. Doing so would, in the view of this author, be a more laudable goal – and a truly more exciting challenge – than the current emphasis on replication, for ever expanding markets, of outdated learning structures by new means.

**Implications at the level of inter-institutional collaboration**

While in some parts of the world there may seem to be no limit to the extent of the resources that can be brought to bear on addressing the problems of human learning, whosoever
takes the trouble to look at the world at large will soon discover that there is an important challenge in creating sustainable solutions that benefit large numbers of people. Sustainability in this context means that the cost of what we do at a particular time will not be charged to a future we are unable or unwilling to visualize or take responsibility for. It should also be noted that solutions that benefit many people do not necessarily have to rely on mass-produced and mass-delivered options.

There is enormous potential for promoting and facilitating learning in the networking of those who have a passion to learn (e.g. Rossman, 1993). This applies to both individuals and institutions. Anything that detracts from the likelihood that inter-institutional collaboration would occur, such as the artificial opposition between learning at a distance and in the face-to-face mode, is thus counter to exploring this potential.

The tendencies of some institutional environments towards expansion (e.g. Daniel, 2000, July), sometimes through the merger with smaller entities, may seem to contribute to creating larger networks. However, there is the risk that the strong presence of large conglomerates reduces the diversity of the learning landscape, thus taking away one of the most powerful resources in the learning habitat. To the extent that the learning landscape functions in ecologically sound ways, in other words, to the extent that diverse sub-landscapes are the active ingredients of the learning landscape, such homogenizing forces may be counteracted by heterogeneous dialogues resulting from interaction with different ideological and cultural traditions (Appadurai, 1990).

There may, as yet, not be enough evidence to draw conclusions as to how the various tendencies towards globalization will affect diversity. It would be prudent, though, to keep an open eye towards what may be happening and to assess such possible impact on an ongoing
basis. It is equally prudent to encourage ways of networking that deliberately thrive on diversity, i.e. multi-nodal collaboration among institutions that have a distinct identity, as opposed to building networks that are run out of a central node.

Against the backdrop of the above cautionary remarks, I posit that increased networking around the globe is an important condition for the formation of dynamic learning communities that are sufficiently global in outlook to become a basis for learning to live together (Delors et al., 1996) with the global concerns of our time. For this to be possible, those collaborating institutions must once again become what they used to be: universities, places of inquiry not limited by the boundaries of bureaucracy and traditional divisions among disciplines. UNESCO’s UNITWIN/UNESCO Chairs (n.d.) program is an interesting example in the above regard.

Implications at the institutional/organizational level

The closing observation in the previous paragraph is also the first recommendation under the present heading. The model of monolithic, bureaucratized and compartmentalized institutions dominates the institutional heritage of the 19th and 20th centuries. Such institutions now find themselves in need of becoming players in a networked environment, often having great difficulty to respond adequately to the challenge.

In using the term “universities” above, I do not intend to restrict my considerations to higher education institutions. The connection between higher education and higher learning, i.e. learning at a higher level of metacognitive awareness and capability, is rather weak, whence the meaning of the adjective “higher” in higher education seems to have little relevance as a qualifying concept for the kind of learning that is promoted by higher education institutions.
To play an effective role in shaping the increasingly networked learning landscape of the 21st century, institutions whose mission is to promote and facilitate learning must enhance their ability to interact constructively with their changing environment. In terms of the redefinition of learning called for in this chapter and proposed in formal terms elsewhere (J. Visser, 2001), this means that such institutions must conceive of themselves as learning organizations. The literature in this area is vast and now so well known that there is hardly a need to mention such names as Senge (1990); Argyris (1993); Senge, Kleiner, Roberts, Ross and Smith (1994); Marquardt (1996); or Hesselbein, Goldsmith and Beckhard, Eds. (1997).

The change of attitude implied in becoming a learning organization should go hand in hand with the development of systemic awareness and abilities in the institution, both in terms of its internal processes and with regard to its role vis-à-vis other institutions and the learning landscape at large. It must equally focus on the profoundly human (as contrasted with bureaucratic) mission inherent in fostering learning, a particularly acute challenge for institutions whose traditions are rooted in the philosophy of the industrial era (Peters, 1994). Clearly, this is a change that affects everyone in the institution: students, faculty, administrative staff, as well as management.

**Implications at the learning process level**

The most important implications are at the level of the learning process itself. Very little impact on our ability to deal with global issues and concerns is likely to result from our continued preoccupation with knowledge as a thing, as opposed to knowledge as a process. To reorient the learning process away from its habitual focus on acquiring isolated pieces of knowledge, the overriding vision in learning must be on problems (e.g. Jonassen, 1994; Hmelo,
1998; Bransford, Brown & Cocking, 1999 [particularly Ch. 2]), transdisciplinarity (Nicolescu, 1996 & 1999, April), and consilience (Wilson, 1998).

Reintroducing this overriding concern in our conscious efforts to promote the development of human learning does not mean a radical doing away with everything that has to do with disciplines, content-based curricula, or even rote learning of particular facts. There is abundant evidence to support the idea that such things have their relative usefulness. However, that usefulness gets reduced when it is the only focus in learning and when it cannot be embedded in a larger frame of relevance.

The overall focus on problems, transdisciplinarity and consilience is a vital condition, also, for learning to become, once again, dialogue. It is equally a prerequisite for the development of critical thinking, creativity, and the socialization and contextualization of cognition. Moreover, placing students, and those with whom they learn, eye-in-eye with the real world of whole problems and interconnected knowledge and associated emotions regarding those problems, will be most beneficial to bring back yet another important aspect of our humanity in the learning process: The fact that we function with our entire bodies; not just the neocortex.

The challenge to the distance education community in considering the above implications lies in the need to move past the customary rhetoric of cost-effectiveness and economies of scale. Such notions are based on the idea that the existing principles of instruction are adequate and merely require the redesign of the processes of their application to benefit larger audiences in affordable ways. I have tried to argue that the problems with the development of learning in the context of today’s challenges are much more complex and fundamental. They require the field to be reinvented. The difficulty in meeting that challenge is rather psychological than substantial. The problems are known and the tools are there.
